

VARIATIONS IN THE SENSITIVITY OF *LISTERIA MONOCYTOGENES* TYPES TO LACTIC ACID BACTERIA BACTERIOCINS

MIRJANA DIMITRIJEVIĆ, V. TEODOROVIĆ, M. BALTIĆ and M. MIRILOVIĆ

*Faculty of Veterinary Medicine, Beograd, Yugoslavia*

(Received, 5. October 1998.)

*Listeria monocytogenes* is a cause of human and animal listeriosis, a disease which is often lethal. Food of animal origin is a very important carrier in human infection. This microorganism was found in many foodstuffs during the last decade in numerous studies. As a basic precaution for providing consumer food safety, investigations are directed toward the greatest reduction of the number of undesirable and pathogenic microorganisms in food. Thus, the sensitivity of *Listeria monocytogenes*, both clinical/human strains (50) and those found in food of animal origin (48), to lactic acid bacteria bacteriocins was examined at two incubation temperatures (37°C/24h and 4°C/12 days). Namely, it is well known that not only closely related bacterial species, but also less closely related Gram positive bacteria, may have bactericidal or bacteriostatic proteins or protein molecules to *L. monocytogenes*. Then they can be eventually added to food, with the aim of decreasing the risk of listeriosis to the minimum. It was found that bacteriocins, originating from *Lactococcus* UW and *Lactobacillus* sake 148 did not express inhibitory effects on any of the *Listeria* strains. However, bacteriocins originating from *Lactobacillus* sake 265, *Pediococcus* 347 and *Lactobacillus* sake 706 had listericidal effects on almost every analyzed type. The highest bactericidal effect was expressed by bacteriocins from *Lactobacillus* sake 265. There was statistically a very significant difference ( $p < 0.01$ ) and a significant difference ( $p < 0.05$ ) between the arithmetic mean values for inhibition zones with clinical/human strains and those originating from foodstuffs. It was found that the incubation time and temperature influenced the inhibitory effects of bacteriocins, too.

**Key words:** *Listeria monocytogenes*, bacteriocins, lactic acid bacteria, temperature treatment, sensitivity.

## INTRODUCTION

Direct or indirect contamination of food with many microorganisms, leads to serious disease in humans, which may be lethal (Dimitrijević and Teodorović, 1998). One species which is of current interest, is *Listeria monocytogenes*, the cause of listeriosis, for which food of animal origin is often a carrier of infection (Farber and Peterkin, 1991; Bunčić, 1991; Bunčić et al., 1995). Great epidemics of listeriosis in humans have occurred after consumption of food of plant origin, milk and dairy products, as well as meat and meat products (Bader, 1993). The ubiquitous nature of *Listeria monocytogenes* makes very unreal the total exclusion of initial contamination of food (Gahan and Collins, 1991). This indicates the extraordinary importance of knowing well the factors which may reduce its numbers in foodstuffs (Crawford, 1989). Lactic acid bacteria, assigned as health safe microorganisms, are used in food, not only for achieving useful metabolic and sensory changes, but also for their invaluable important protective role, because they have a negative influence on numerous undesirable microorganisms. They achieve their protective role by competition for food and/or by producing bacteriocins and other antimicrobial substances (Klaenhammer, 1993). Bacteriocins are extracellularly released peptides or protein molecules, produced by lactic acid bacteria, which have bactericidal and bacteriostatic effects, usually towards closely related bacterial species (Jack et al., 1995). However, it was found that they may have destructive effects on some unrelated, Gram positive bacterial species among which is *L. monocytogenes* (Muriana, 1996). Taking into account that *L. monocytogenes* is a cause of serious human disease, for which the minimal infective dose is not yet known, and its ubiquitous nature and widespread distribution in foodstuffs it was considered interesting to assess its sensitivity to lactic acid bacteria bacteriocins, which can be eventually added to the food (Eckner, 1992; Teodorović, 1996).

## MATERIALS AND METHODS

A collection of 98 strains of *L. monocytogenes* consisting of 50 clinical/human strains and 48 strains from foodstuffs of animal origin was made. The clinical/human types originated from blood, liquor, infected human feces (carriers or ill persons). Other strains were isolated and identified from foodstuffs of animal origin by the method of McLain and Lee (1989). Bacteriocins from the following lactic acid bacteria were examined: *Lactococcus* UW, *Lactobacillus* sake 148, *Lactobacillus* sake 265, *Pediococcus* 347 and *Lactobacillus* sake 706. Assessment of growth inhibition of various types of *L. monocytogenes* by the bacteriocins was performed by the diffusion method from wells into. Every type was assessed in triplicate in order to provide adequate accuracy and precision of the results. Two incubation procedures were used: 37°C for 24 hours and 4°C for 12 days. The results were expressed as the mean values for inhibition zone diameter (mm) for each strain. The statistical significance of differences between procedures and strain origin calculated by the random plan method using statistical software (Statgraphics 5.0; Statistical Graphic Corporation USA).

Table 1. Sensitivity of *L. monocytogenes* types, clinical/human types, related to the bacteriocins of lactic acid bacteria

| Sign          | Lactobacillus sake 265    |                          | Pediococcus 347           |                          | Lactobacillus sake 706    |                          |

## RESULTS AND DISCUSSION

Undeniably some bacteriocins originating from lactic acid bacteria may have bactericidal or bacteriostatic effects, towards both closely related bacterial species, and also towards less closely related Gram positive species such as *L. Monocytogenes* (Dimitrijević, 1998). In our study it was found that those bacteriocins originating from the chosen lactic acid bacteria did not express an inhibitory effect on the tested types of *L. monocytogenes* in all cases (Table 1 and 2).

Table 3. Statistical significance of differences between mean inhibition zones for clinical/human types of *L. monocytogenes* and types from foodstuff after 24 hours at 38°C in the presence of three bacteriocins

\*\*  $p < 0.01$  (significance at 99%)

Figure 1. Sensitivity variations of *L. monocytogenes* types to lactic acid bacteria bacteriocins at 37°C/24h

Bacteriocins from *Lactococcus* UW and *Lactobacillus* sake 148 did not express bactericidal activity in any case. Bacteriocins from *Lactobacillus* sake 265, *Pediococcus* 347 and *Lactobacillus* sake 706 expressed bactericidal effects on all except a small number of tested strains of *L. monocytogenes*. It was found that there was no statistically significant difference between the arithmetic mean values for inhibition zones, with clinical/human types and types from foodstuffs after 24 hours at 37°C, (Table 3, Figure 1.) in relation to the assessed bacteriocins ( $p < 0.05$ ). However, at a cooler temperature (4°C) for 12 days, it was found that there were statistically significant, differences in the inhibitory effects of bacteriocins originating from *Lactobacillus* sake 265, and *Pediococcus* 347, in favor of clinical/human types (Table 4, Figure 2). On this basis it can be claimed, with 99% ( $p < 0.01$ ), and 95% ( $p < 0.05$ ) probability that, bacteriocins originating from *Lactobacillus* sake 265, and *Pediococcus* 347, respectively will express a greater inhibitory effect towards clinical/human types than towards types originating from foodstuffs of animal origin.

\*\*  $p < 0.01$  (significance at 99%)

\*  $p < 0.05$  (significance at 95%)

Analysis of the results obtained the for sensitivity of all *L. monocytogenes*, types regardless of their origin, towards the bacteriocins which expressed listericidal effects, indicated statistically significant differences. Thus during incubation at 37°C for 24 h, bacteriocins from *Lactobacillus* sake 265, *Pediococcus* 347 and *Lactobacillus* sake 706 expressed inhibitory effects towards all tested types of *Listeria* with statistically very significant differences between the arithmetic mean values of inhibition zones ( $p < 0.01$ ). At the cooler temperature of 4°C 12 days these bacteriocins also expressed listericidal effects, with statistically highly significant differences ( $p < 0.01$ ), in all cases, except for bacteriocins from *Pediococcus* 347, where the difference was statistically significant only ( $p < 0.05$ ). The ability to produce bacteriocins was found for a number of strains of *Lactobacillus* sake (laktacin S, sakacin A, sakacin P, sakacin 148) which have listericidal effects. Our experiments have shown that two strains of these lactic acid bacteria (*Lactobacillus* sake 265, and *Lactobacillus* sake 706) produce bacteriocins that have inhibitory effects on the assessed *Listeria*. The effects were greater at a cool temperature over a long period. Bacteriocins originating from

Figure 2. Sensitivity variations of *L. monocytogenes* types to lactic acid bacteria bacteriocins at 4°C/12 days

*Lactobacillus sake* 265 gave much greater inhibition zones (1.43-5.65 mm) than bacteriocins originating from *Lactobacillus sake* 706 (0.76-1.88), which had the lowest listericidal effect. *Pediococcus* 347 expressed a very uniform listericidal effect (1.88-2.44 mm) both at the cool temperature (4°C for 12 days) and at 37°C for 24 h. However, it was suggested that pediococci also produce some acids, as metabolic products, which might inhibit the growth of *Listeria* (Raccach and Geshel, 1993), but we excluded that possibility by using separated bacteriocin. On the basis of the data presented the addition of lactic acid bacteria bacteriocins to food should be considered in the future, with the aim of reducing the eventual presence of *Listeria* in foodstuffs of animal origin and therefore lowering the risk of alimentary listeriosis to a minimum.

#### VARIJACIJE OSETLJIVOSTI SOJEVA *LISTERIA MONOCYTOGENES* PREMA BAKTERIOCINIMA MLEČNOKISELINSKIH BAKTERIJA

MIRJANA DIMITRIJEVIĆ, V. TEODOROVIĆ, M. BALTIĆ I M. MIRILOVIĆ

#### SADRŽAJ

*Listeria monocytogenes* je uzročnik listerioze ljudi i životinja, oboljenja koje se često završava letalno. Namirnice animalnog porekla su veoma važan vektor u nastanku infekcije ljudi. Tokom poslednje dekade mnogobrojnim istraživanjima ustanovljeno je prisustvo ovog, inače ubikvitarnog mikroorganizma, u velikom broju namirnica. Kako je higijenska ispravnost namirnica animalnog porekla osnovni preduslov za obezbeđivanje zdravstvene bezbednosti i sigurnosti potrošača, nastojanja su usmerena na što većoj redukciji prisustva nepoželjnih i patogenih mikroorganizama u hrani. U ovom radu ispitivana je osetljivost sojeva *L. monocytogenes*, kliničkih/humanih (50) i sojeva poreklom iz namirnica (48) prema bakteriocinima mlečnokiselinskih bakterija, pri dve temperature inkubacije (37°C/24h) i 4°C/12 dana). Naime, poznato je baktericidno i bakteriostatsko dejstvo ovih proteina ili proteinskih molekula ne samo prema srodnim bakterijskim vrstama, već i prema manje srodnim Gram pozitivnim bakterijama, kao što je *L. monocytogenes*, te bi se eventualno mogli dodavati u hranu, u cilju smanjenja rizika od listerioze na minimum. U radu je ustanovljeno da bakteriocini poreklom od *Lactococcus* UW i *Lactobacillus* sake 148 nisu ispoljili inhibitorni efekat ni prema jednom soju listerija, dok su bakteriocini poreklom od *Lactobacillus* sake 265, *Pediococcus* 347 i *Lactobacillus* sake 706 imali listericidni efekat skoroprema svim ispitivanim sojevima. Najveće baktericidno dejstvo ispoljio je bakteriocin poreklom od *Lactobacillus* sake 265. Postajala je statistički vrlo značajna ( $p < 0.01$ ), odnosno značajna razlika ( $p < 0.05$ ) između aritmetičkih sredina zona inhibicije kliničkih/humanih i sojeva poreklom iz namirnica. Takođe ustanovljeno je da je temperatura inkubacije uticala na inhibitorne efekte bakteriocina.
